

US Inspection Modernization

May 2026

Inspection Modernization

Background

- The Food Safety and Inspection Service (FSIS) has been committed to modernizing the way in which they conduct inspection in our facilities.
- FSIS completed modernized inspection in poultry plants. (2014).
- FSIS is now expanding modernized inspection to livestock facilities.
- Poultry and swine modernization are codified in US regulations.
- Beef modernization is permitted under a regulatory waiver.

DISCUSSION POINTS

Inspection Modernization at Pork Plants

- In 2019, FSIS finalized a regulation for modernized inspection in pork.
 - Certain requirements apply to all our pork facilities (process control programs that include microbiological sampling procedures for indicator organisms) and voluntary participation in other portions of the regulation (pre-sorting carcasses for diseases).
 - FSIS was sued over pork modernization. Court upheld sorting activities – but indicated linespeed component violated the Administrative Procedures Act. FSIS has a 3rd party evaluating linespeed under modernized system/
- FSIS has requested industry to voluntarily submit regulatory waivers for modernization of beef inspection. This will allow for data collection by FSIS such that they can promulgate similar regulations for all beef plants in the future.
- Modernization for all species has been controversial with FSIS inspectors and consumer groups. The controversy stems from the loss of “unionized” jobs. The “public face” to the controversy is employee safety. FSIS requires industry to address employee safety as part of their required programs.

What is Modernized Inspection in the United States?

Industry conducts pre-sorting at ante and post-mortem so that only healthy animals and carcasses are presented to FSIS for inspection.

FSIS can have less inspection personnel stationed on the line – and still complete 100% carcass inspection.

FSIS to be able to leverage additional resources towards food safety and animal welfare inspection tasks.

Industry has the flexibility to have more control over their process and data.

EXAMPLE of Traditional Inspection

Off-Line Inspection Protocol

In practice, there is typically one FSIS inspector to conduct off-line inspection tasks. There is also one FSIS PHV to supervise inspectors and inspect for animal disease conditions. A PHV supervises inspectors and inspects for animal disease conditions.

On-Line Inspection Protocol

For traditional swine inspection, there are up to seven FSIS inspectors total. The below graphic illustrates an example of how a line might look.

- FSIS food safety inspectors (FI) direct plant employees to make cuts and trim defects. FSIS food safety inspectors are the only personnel responsible for inspection.

This graphic is for illustrative purposes only. Each establishment is configured differently and the number of FSIS inspection personnel will vary per plant.

EXAMPLE of Modernized Inspection

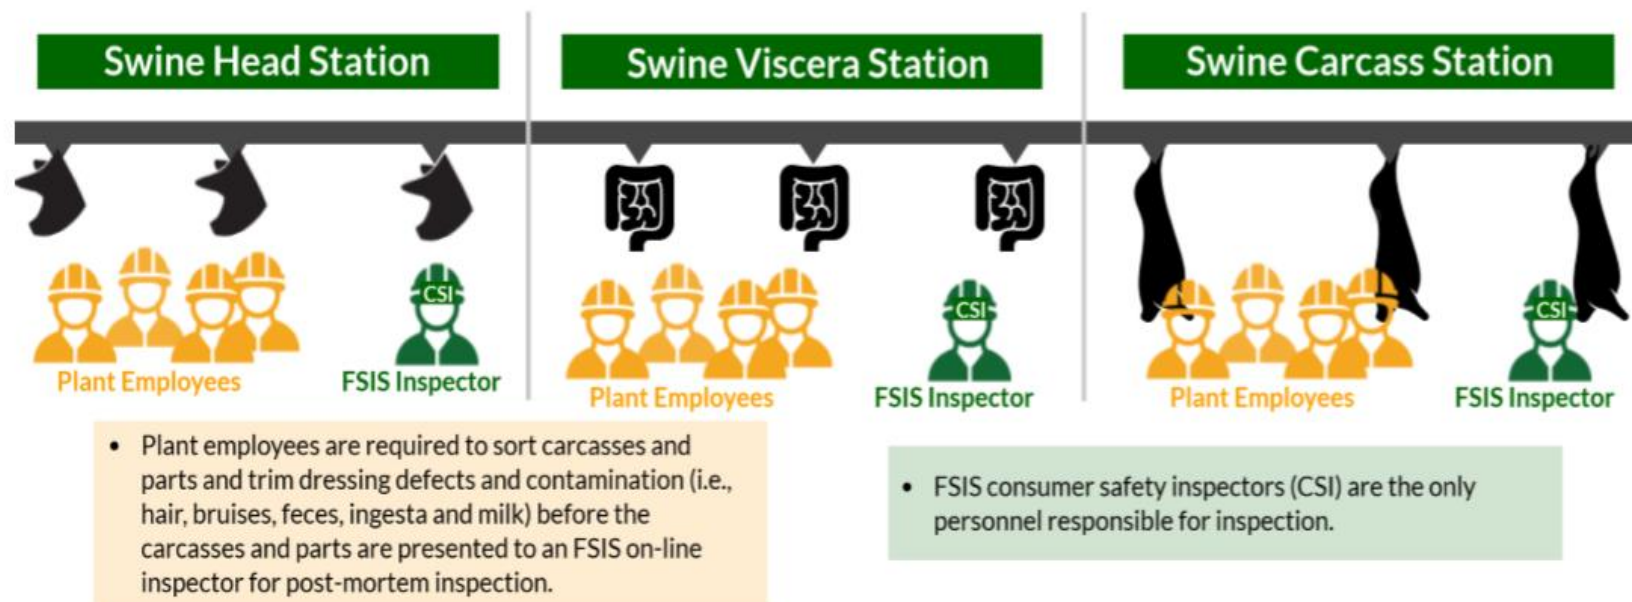

Off-Line Inspection Protocol

In the proposal we state that up to **one public health veterinarian (PHV)** and **two FSIS inspectors** are **off-line**. A PHV supervises inspectors and inspects for animal disease conditions.

FSIS Veterinarian **FSIS Inspectors**

On-Line Inspection Protocol

For modernized swine inspection, there are up to three FSIS inspectors total. The below graphic illustrates an example of how a line might look.

This graphic is for illustrative purposes only. Each establishment is configured differently and the number of FSIS inspection personnel will vary per plant.

* As suggested, the configuration will vary at each facility. This example suggests that there may be fewer overall personnel involved. For most companies, between Team Members and FSIS there will be more overall personnel.

Ante-mortem Sorting Process

- Allow on to FSIS Inspection: normal, healthy hogs
- Hold for Further Sorting and/or FSIS Inspection: abnormal hogs that may be healthy enough for slaughter. Must be segregated away from normal hogs for evaluation by a lead sorter and inspection by the FSIS PHV.
- Discard: unhealthy, injured, or unfit hogs. Must be humanely euthanized in a timely fashion and disposed of according to company policy.
 - Dead
 - Moribund: Animals in the act of dying. Look for inactivity, loss of awareness of surroundings, abnormal skin color (blotchy or blue discolorations), gasping, frothy mouth and/or nasal discharge, unable to rise and walk.
 - Central nervous system (CNS) diseases. Look for seizures, convulsions, abnormal gait (circling, dizziness, loss of balance), difficulty swallowing, abnormally excited or aggressive behavior, head pressing or head tilt. FSIS is notified to observe animal prior to euthanasia.
 - Febrile. Hogs with an elevated body temperature are febrile - body temperature is 106° F or higher.

Post-mortem Sorting

Sorter To Condemn

Systemic Food Safety Conditions

Septicemia

(sepsis, septic)

Bacteria enters the blood and spreads to other parts of the body.

Toxemia

(toxic, toxin)

Toxins released by bacteria travel throughout the body.

Pyemia

(pus)

A type of septicemia.

Pus-forming bacteria cause multiple abscesses.
